

RADIO TELECOMMUNICATIONS NETWORK, USER EQUIPMENT AND METHOD OF OPERATION

Cross Reference To Related Application

5 This application claims priority of Great Britain Application No. GB0027697.2 filed on November 13, 2000.

Background Of The Invention

Field of the Invention

10 This invention relates to a radio telecommunications network, to user equipment for the network and to a method and program for operating the equipment and the network.

Description of Related Art

The background to invention will be explained against the applicants' realisation that even in second generation networks all known planned services are near real time.

SUMMARY OF THE INVENTION

15 Against this background there is provided battery operated user equipment for use in a radio telecommunications network, including means for monitoring the state of charge of the battery and means for communicating state of charge data to a base station. A preferred embodiment includes a data store and means for configuring the
20 equipment to receive files automatically and store them in the data store, or to retrieve files from the data store and transmit them, without activating any sounder or vibrator for alerting the user. A very significant advantage of such an arrangement is that files for which immediate delivery is not important, can be sent at times when activity on the network is low, e.g. at night. More broadly, however, the battery data can be used to
25 inform a caller that, for example, a called user's apparatus has reduced or limited battery capacity and thus that the expected duration of a call is limited.

In the preferred example, in order that the user shall not be disturbed by unwanted conventional calls e.g. at night, user input means is preferably provided selectively barring set up of calls which require alerting a user.

The preferred equipment may include a data storage capacity monitor for
5 monitoring the available data storage capacity of the data store and for communicating available storage capacity data to the base station.

The equipment preferably includes means for estimating which one of a plurality of available physical channels would best conserve battery charge, and for signalling the identity of that channel to the base station.

10 The invention extends to a radio telecommunications network including battery operated user equipment, which equipment includes means for monitoring the state of charge of the battery; a data store; means for configuring the equipment to receive files automatically and store them in the data store, or to retrieve files from the data store and transmit them; and means for monitoring the available data storage capacity of the data
15 store, the network including: means for estimating whether the state of charge of the battery and/or the available data storage capacity is/are sufficient to allow reception or transmission of each file, with or without a predetermined reserve, and for denying reception or transmission if the state of charge or the available data storage is insufficient.

20 The invention also extends to a method of operating user equipment in a mobile communication network, comprising setting up a call to receive and store data without making any user alerting signals unless on a display.

The invention further extends to a computer program for carrying out all the steps of the method.

25 **BRIEF DESCRIPTION OF THE DRAWINGS**

Embodiments of the invention will now be described, by way of example, with reference to the accompanying drawing, in which:

Figure 1 is a block diagram of user equipment embodying the invention; and

Figure 2 is a block diagram illustrating a method of operation of a network and user equipment embodying the invention.

DETAILED DESCRIPTION

Referring to the drawing, a processor 2 sends user data and signalling information for transmission by a transmitter 4 on both user channels and common channels. The transmitter 4 sends modulated radio frequency signals to a power amplifier 6 and via a duplexer 8 to an antenna 10. Common channel and user channel radio signals received by the antenna 10 are sent via the duplexer to a receiver 12, where data signals are recovered and sent to the processor 2.

Data can be input to the processor via a keypad 14, e.g. for initiating a call.

Information can be displayed by the processor on a display screen 16, e.g. that the unit is in communication with a network, remaining battery capacity, a directory number input from the keypad etc.

The user equipment is provided with a writable data store 20 e.g. in the form of a flash memory. A program store 22 contains an interface to enable the processor to read and write the data store 20 and to monitor its spare capacity.

Conventionally, when an attempt is made over a common channel to set up a call, signals are sent from the processor to audio circuits 18 which drive transducer 24 to generate an audible tone. In the present user equipment, to implement wireless offline transfer (WOLFT), special signalling on the common channel can set up a call without activating the transducer 24 although visible (silent) signals may be displayed on the screen 16. The call set up information can specify that data (a file e.g. e-mail) to be sent

in a user channel on the downlink is to be stored in the data store 20. The set up information may specify the file size. Software stored in the program store 22 is arranged to determine whether or not the available capacity of the data store is sufficient to contain the file and to refuse or discontinue the call if it is not. In an alternative, during
5 call set up, available capacity of the data store 20 is transmitted on the uplink and a decision as to whether or not to send the file being made in the network e.g. in the radio resource control (RRC) layer. In general, There is sufficient spare capacity on the common channels to accommodate the extra signalling.

The user equipment is powered by a battery 26. Before transmitting a long file to
10 the user equipment, it is relevant to know whether the battery has sufficient life available to enable the full file to be received. To this end a voltage sensor 28 communicates with the processor 2. From the battery voltage, the processor 22 performs a calculation based on an estimate of the power usage during transfer of the file, and on the size of the file and data transfer rate, to determine whether there is sufficient battery life
15 available to receive the full file. In an alternative, it is determined whether there would be a predetermined minimum life left after receiving the file. If either condition is not fulfilled, the call is refused or terminated. In an alternative, data indicating the battery voltage or battery life is transmitted on the common channel during call set up and the decision is made by the network in the RRC layer.

20 If more than one user data channel is available, the processor is arranged to assess use of that which would make least drain on the battery , e .g .by requiring least power and/or giving greatest data transfer rate, and to select that channel.

The software stored in the program store 22 is responsive to user input from the keypad 14 to disable the transducer, audio circuits 18, or bar set up of calls requiring
25 operation of the transducer 24, leaving the user equipment responsive to common

channel signalling to set up a call in which the transducer is not sounded and in which a data file, e.g. e-mail, can be silently downloaded to the data store 20.

The network may be set to provide file transfer service, e.g. e-mail to be delivered by 8:00 the next day at times which are convenient to it e.g.:

5 a) The network load is very low.

b) Assuming sufficient temporal variation in the traffic load across the air-interface, there will be times (e.g. at night) when there is spare air-interface capacity (spare time-slots for 2G TDMA systems and spare power for 3G CDMA systems). This spare capacity could be particularly efficiently used by WOLFT on the DL.

10 c) The radio channel propagation characteristics are extremely favourable. An example of when this could occur are when the mobile is very close to the base station or when the mobile is no longer moving at high speed. With statistics regarding the users habit the network or wireless equipment may even be able to predict when the radio conditions may be most favourable for UL or DL WOLFT.

15 d) The mobile has the capacity to receive/transmit the complete message. An example of exclusion would be when the mobile has insufficient battery or storage capabilities to enable the UL or DL WOLFT to be completed.

e) The user equipment user places the equipment into a "WOLFT enabled mode". This could occur when the mobile user wishes to go to sleep and places the
20 mobile into a "Stand by do not disturb Sleep mode".

f) To prevent overload of the storage buffers of the network.

Referring to Figure 2, the network sends a request to transmit a non delay sensitive file of size X (e.g. for delivery before 8.00 am the next day). The request is received by the user equipment in block 30. The user equipment is asked to notify the

network when one or more of the following conditions are met: 1) the user equipment has not notified the radio network of a location (e.g. cell) update for a predetermined time which may be specified in the request; 2) the radio link quality between the user equipment and the BTS is very good (e.g. the user equipment is very close to the BTS
5 and the traffic load is low; and 3) the storage capacity of the user equipment is greater than X.
